DGN DGN is a specification to store and exchange geographic data. DGN stands for Digital Geospatial Network. The specification has been adopted by the International Association of Oil & Gas Producers (IOGP). DGN is used as a standard interchange format between the GIS components of the oil and gas industry. The standards encompass 3D modelling, geospatial analysis, geospatial modelling, data transfer, and database integration. DGN is the recommended format for exporting and importing GIS data between systems. It is also used for data exchange between GIS software and the Internet. However, the data can also be exchanged between GIS software and other software. DGN uses a hierarchical model to represent GIS data. The layer types are Layer, Feature and Shapefile. An attribute table is created to store attribute information. The attribute table and shapefile are stored in a file named "DGN". A GIS application can access an exported or imported DGN file by following the instructions in the DGN specification, therefore creating and editing a DGN file is similar to GIS data exchange. DGN data can be automatically imported from an ASCII text file. DGN data can also be imported into most GIS software using ArcGIS, MapInfo, or ESRI's ArcView, which have either native or compatible plug-ins for DGN data import. The DGN data is independent of the shapefile format and can be stored with different formats like CSV, XML, Oracle Spatial, DBF, or SQLite. Some GIS software has been developed to handle DGN files: GeMapViewer — provides reading of GeoDatabase, DGN files and converting them into ArcGIS shapefiles GEE — provides reading of GeoDatabase, DGN files and converting them into ArcGIS shapefiles GeoTools — provides reading of GeoDatabase, DGN files and converting them into ArcGIS shapefiles Geoportal — GIS database management software for Windows and Linux. Nos. 4,842,234 and 4,898,524 describe a process for the production of a stabilized multi-component mixture containing polyisocyanates and polyhydroxyl compounds, which comprises reacting an organic compound having at least two active hydrogen atoms with a polyisocyanate in a two-stage process. In the first stage, a reaction product is obtained by the reaction of the organic compound having at least two active hydrogen atoms with an excess of polyisocyanate. In the second stage, a polyhydroxyl compound is added to the reaction product obtained in the first stage. In the method described in U.S. Pat. No. 4,842,234, the mixture of isocyanate and polyol is prepared in two stages. In the first stage, the reaction between the organic compound having at least two active hydrogen atoms and the polyisocyanate is performed in a fixed-bed reactor with a very long residence time and with a relatively small excess of polyisocyanate. This means that, in the process, very large amounts of unreacted polyisocyan
